SUPERCONVERGENCE OF THE VELOCITY IN MIMETIC FINITE DIFFERENCE METHODS ON QUADRILATERALS

M. BERNDT†¶, K. LIPNIKOV†¶, M. SHASHKOV†¶, M. F. WHEELER‡∥, AND I. YOTOV§∗∗

Abstract. Superconvergence of the velocity is established for mimetic finite difference approximations of second-order elliptic problems over $h^2$-uniform quadrilateral meshes. The superconvergence result holds for a full tensor coefficient. The analysis exploits the relation between mimetic finite differences and mixed finite element methods via a special quadrature rule for computing the scalar product in the velocity space. The theoretical results are confirmed by numerical experiments.

Key words. mixed finite element, mimetic finite difference, tensor coefficient, superconvergence

1. Introduction. We consider the numerical approximation of a linear second-order elliptic problem. In porous medium applications, this equation models single phase Darcy flow and is usually written as a first-order system for the fluid pressure $p$ and velocity $u$:

$$
\begin{align*}
\mathbf{u} &= -K \nabla p, & \text{in } \Omega, \\
\text{div } \mathbf{u} &= f, & \text{in } \Omega, \\
\mathbf{u} \cdot \mathbf{n} &= g, & \text{on } \partial \Omega,
\end{align*}
$$

where $\Omega \subset \mathbb{R}^2$, $\mathbf{n}$ is the outward unit normal to $\partial \Omega$, and $K \in \mathbb{R}^{2 \times 2}$ is a symmetric uniformly positive definite full tensor representing the rock permeability divided by the fluid viscosity. We assume that the system (1.1) satisfies the compatibility condition

$$
\int_{\Omega} f \, dx + \int_{\partial \Omega} g \, ds = 0.
$$

In this paper, we analyze the convergence of a mimetic finite difference (MFD) method on quadrilateral meshes. The method uses discrete operators that preserve certain critical properties of the original continuum differential operators. Conservation laws, solution symmetries, and the fundamental identities and theorems of vector and tensor calculus are examples of such properties. This “mimetic” technique has been applied successfully to several applications including diffusion [22, 15, 18], magnetic diffusion and electromagnetics [14], continuum mechanics [17], and gas dynamics [8]. For problem (1.1), the mimetic technique uses discrete flux $\mathcal{G}$ and divergence $\text{DIV}$ operators for the continuum operators $-K \nabla$ and $\text{div}$, respectively, which are adjoint to each other, i.e. $\mathcal{G} = \text{DIV}^*$. It is straightforward to extend the MFD method to locally refined meshes with hanging nodes [16], unstructured three-dimensional

meshes composed of hexahedra, tetrahedra, and any cell type having three faces intersecting at each vertex.

A connection between the MFD method and the mixed finite element (MFE) method with Raviart-Thomas finite elements has been established in [4]. In particular, it was shown that the scalar product in the velocity space proposed in [15] for MFD methods can be viewed as a quadrature rule in the context of MFE methods. Another closely related method is the control-volume mixed finite element method [7, 9].

MFE discretizations on quadrilateral grids have been studied in [25, 26, 2, 13]. These methods are based on the Piola transformation [25, 6], which preserves continuity of the normal component of the velocity $u$ across mesh edges. Unfortunately, this results in the necessity to integrate rational functions over quadrilaterals. The task becomes even more complicated, when the diffusion tensor is full and non-constant. The results in [4] provide an efficient numerical quadrature rule with a minimal number of points. Moreover, the connection between the two methods allows for extensions of MFE methods to general polygons and polyhedra.

The aforementioned connection provides a suitable functional frame for rigorous analysis of convergence of mimetic discretizations. In [4], first order convergence for the fluid pressure and velocity was shown. In this paper, we establish velocity superconvergence for MFD discretizations of (1.1) on $h^2$-uniform quadrilateral meshes (as defined in (2.2)–(2.3)). Precise calculation of the fluid velocity is important for porous media and other applications. The points or lines where the numerical solution is super-close to the exact solution may be used to improve the accuracy of the overall simulation. Various superconvergence results for mixed finite element methods have been established for rectangular meshes [21, 19, 27, 10, 11, 12, 3, 1] and general quadrilateral meshes [2, 13].

In [13], velocity superconvergence is established for MFE discretization of (1.1) on $h^2$-uniform quadrilateral grids. In this paper, we exploit the relation between MFD methods and MFE methods with quadrature rule (3.10) to establish superconvergence for velocities in MFD discretizations. In particular, we show that the computed normal velocities are super-close to the true normal velocities at the midpoints of the edges. In [18], an alternative quadrature is introduced, which preserves symmetry of the exact solution on polar grids. This symmetry preservation is important for problems of radiation transport in the asymptotic diffusion limit. The analysis of superconvergence for symmetry-preserving quadratures is left to future investigation.

The paper outline is as follows. In Section 2, we describe the MFE method for (1.1). In Section 3, the MFD method is presented and related to the MFE method with quadrature rule. The main superconvergence results are presented in Section 4. Superconvergence of the normal velocities at the midpoints of the edges is established in Section 5. In Section 6, numerical experiments are given that confirm the theoretical results.

2. **The mixed finite element method.** To simplify the exposition, we assume without loss of generality that $g = 0$, i.e. homogeneous Neumann boundary conditions are imposed on $\partial \Omega$.

Throughout this paper, we shall use notations $\| \cdot \|_{k,D}$, $\| \cdot \|_{\text{div},D}$ and $\| \cdot \|_D$ for the norms on the Hilbert spaces $H^k(D)$, $H(\text{div}; D)$ and $L^2(D)$, respectively, where $D \subset \Omega$. In addition, $\| \cdot \|_{k,D}$ will denote the seminorm on $H^k(D)$. To simplify notations, we shall omit the subscript $D$ when $D = \Omega$. Finally, we denote by $(\cdot, \cdot)$ the $L^2$-inner
product on $\Omega$ of either scalar or vector functions. Let

$$V = \{ v \in H(\text{div}; \Omega) : v \cdot n = 0 \text{ on } \partial \Omega \} \quad \text{and} \quad W = \{ w \in L^2(\Omega) : \int_{\Omega} w \, dx = 0 \}.$$

The variational formulation of (1.1) is as follows: find a pair $(u, p) \in V \times W$ such that

$$\begin{align*}
(K^{-1}u, v) - (p, \text{div } v) &= 0, \\
(\text{div } u, w) &= (f, w), \quad \forall (v, w) \in V \times W.
\end{align*} \tag{2.1}$$

For the discretization of (2.1), denote by $T_h$ a shape-regular partition (see [5, p. 113, Remark 2.2]) of $\bar{\Omega}$ into convex quadrilateral elements of diameter not greater than $h$. For two examples of shape regular grids, see Fig. 6.1. We assume that the grid is $h^2$-uniform. Following [13], the quadrilateral partition $T_h$ is called $h^2$-uniform, if each element is an $h^2$-parallelogram, i.e.,

$$\| (r_2 - r_1) - (r_3 - r_4) \| \leq Ch^2 \quad \tag{2.2}$$

and any two adjacent quadrilaterals form an $h^2$-parallelogram, i.e.,

$$\| (r_2 - r_1) - (r'_2 - r'_1) \| \leq Ch^2, \quad \tag{2.3}$$

where $r'_1$, $r'_2$, $r'_3$, and $r'_4$ are the vertices of the adjacent element (see Fig. 2.1).

For any convex quadrilateral $e$, there exists a bijection mapping $F_e : \hat{e} \to e$, where $\hat{e}$ is the reference unit square with vertices $\hat{r}_1 = (0, 0)^T$, $\hat{r}_2 = (1, 0)^T$, $\hat{r}_3 = (1, 1)^T$ and $\hat{r}_4 = (0, 1)^T$. Denote by $r_i = (x_i, y_i)^T$, $i = 1, 2, 3, 4$, the four corresponding vertices of element $e$ as shown in Fig. 2.2. Then, $F_e$ is the bilinear mapping given by

$$F_e(\hat{r}) = r_1 (1 - \hat{y}) (1 - \hat{y}) + r_2 \hat{x}(1 - \hat{y}) + r_3 \hat{x}\hat{y} + r_4 (1 - \hat{x})\hat{y}. \quad \tag{2.4}$$

Note that the Jacobi matrix $DF_e$ and its Jacobian $J_e$ are linear functions of $\hat{x}$ and $\hat{y}$. Indeed, straightforward computations yield

$$DF_e = [(1 - \hat{y}) r_{21} + \hat{y} r_{34}, \ (1 - \hat{x}) r_{41} + \hat{x} r_{32}] \quad \tag{2.5}$$

and

$$J_e = 2|T_{124}| + 2(|T_{123}| - |T_{124}|)\hat{x} + 2(|T_{134}| - |T_{124}|)\hat{y} \quad \tag{2.6}$$
Since \( e \) is convex, the Jacobian \( J_e \) is always positive, i.e. \( J_e > 0 \).

Let \( \ell_i \) and \( \ell'_i \), \( i = 1, 2, 3, 4 \), be the edges of \( e \) and \( \hat{e} \), respectively. Let \( \mathbf{n}_i \) and \( \mathbf{n}'_i \) be the unit outward normal vectors to \( \ell_i \) and \( \ell'_i \), respectively (see Fig. 2.2). Similarly, let \( \mathbf{r}_i \) and \( \mathbf{r}'_i \) be the unit tangential vectors to \( \ell_i \) and \( \ell'_i \), respectively. It is easy to see from (2.4) that for any edge \( \ell_i \)

\[
\mathbf{n}_i = \frac{1}{|\ell_i|} J_e \mathbf{F}_e^{-T} \mathbf{r}_i \quad \text{and} \quad \mathbf{r}_i = \frac{1}{|\ell_i|} J_e \mathbf{F}_e \mathbf{n}_i. \tag{2.7}
\]

The reader is referred to [6] for suitable choices for the pair of finite element spaces \( V^h \subset V \) and \( W^h \subset W \). In this paper, we consider the lowest order Raviart-Thomas finite element spaces RT0 [25, 20] defined on the reference element \( \hat{e} \) as

\[
\hat{V}(\hat{e}) = P_{1,0}(\hat{e}) \times P_{0,1}(\hat{e}), \quad \hat{W}(\hat{e}) = P_0(\hat{e}),
\]

where \( P_{1,0} \) (or \( P_{0,1} \)) denotes the space of polynomials linear in the \( \hat{x} \) (or \( \hat{y} \)) variable and constant in the other variable, and \( P_0 \) denotes the space of constant functions. The velocity space on any convex quadrilateral \( e \) is defined through the Piola transformation [6]

\[
\frac{1}{J_e} \mathbf{D} \mathbf{F}_e : L_2(\hat{e}) \times L_2(\hat{e}) \rightarrow L_2(e) \times L_2(e), \quad \forall e \in T_h.
\]

The RT0 spaces on \( T_h \) are given by

\[
\begin{align*}
V^h &= \{ \mathbf{v} \in V : \mathbf{v}|_e = J_e^{-1} \mathbf{D} \mathbf{F}_e \mathbf{v} \circ \mathbf{F}_e^{-1}, \mathbf{v} \in \hat{V}(\hat{e}) \ \forall e \in T_h \}, \\
W^h &= \{ \mathbf{w} \in W : \mathbf{w}|_e = \mathbf{w} \circ \mathbf{F}_e^{-1}, \mathbf{w} \in \hat{W}(\hat{e}) \ \forall e \in T_h \}. \tag{2.8}
\end{align*}
\]

Two properties of Piola’s transformation will be important in our analysis. For any \( \mathbf{\hat{v}} \in \hat{V}(\hat{e}) \) and the related \( \mathbf{v} = J_e^{-1} \mathbf{D} \mathbf{F}_e \mathbf{v} \circ \mathbf{F}_e^{-1} \),

\[
J_e \text{div } \mathbf{v} = \text{div } \mathbf{\hat{v}} \quad \text{and} \quad |\ell_i| \mathbf{v} \cdot \mathbf{n}_i = \mathbf{\hat{v}} \cdot \mathbf{n}_i. \tag{2.9}
\]

Note that, since \( V^h \subset H(\text{div}; \Omega) \), any vector in \( V^h \) has continuous normal components on the edges. A function in \( W^h \) is uniquely determined by its values at the cell-centers and a vector in \( V^h \) is uniquely determined by its normal components on the edges. Therefore \( \dim W^h = N_p \) and \( \dim V^h = N_e \), where \( N_p \) is the number of

---

**Fig. 2.2. Bilinear mapping and orientation of normal vectors.**
elements and $N_e$ is the number of interior edges. Let $\{\psi^h_i\}, i = 1, N_p$, be a basis for $W^h$ such that

$$\psi^h_i(c_j) = \delta_{ij} = \begin{cases} 1, & i = j \\ 0, & i \neq j \end{cases},$$

where $c_j$ is the center of element $e_j, j = 1, N_p$. Similarly, let $\phi^h_i, i = 1, N_p$ be a basis for $V^h$ such that $\phi^h_i \cdot n_j = \delta_{ij}$, where $n_j$ is a fixed unit normal vector on edge $\ell_j, j = 1, N_e$. In order to simplify notations, we use the same way for global and local indexing of mesh edges and corresponding normal vectors.

Given the finite element spaces $V^h$ and $W^h$, we define the discrete problem: find $(u^h, p^h) \in V^h \times W^h$ such that

$$\begin{align*}
(K^{-1}u^h, v^h)_h - (p^h, \text{div } v^h) &= 0, \\
(\text{div } u^h, w^h) &= (f, w^h), \quad \forall (v^h, w^h) \in V^h \times W^h, \tag{2.10}
\end{align*}$$

where $(\cdot, \cdot)_h$ is a continuous bilinear form corresponding to the application of a numerical quadrature rule for computing $(\cdot, \cdot)$. A detailed discussion of this quadrature rule is given in Section 3.

3. Mimetic finite difference discretizations. In this section, we derive a mimetic finite difference discretization of equation (1.1) and show its connection with the MFE method (2.10).

The first step in the mimetic technique is to specify discrete degrees of freedom for pressure and velocity. The discrete pressure unknowns are defined at the centers of the quadrilaterals, one unknown per mesh cell. The discrete velocities are defined at the midpoints of mesh edges as normal components. In other words, an edge-based unknown is a scalar and represents the orthogonal projection of a velocity vector onto the unit vector $n_i$ normal to the mesh edge $\ell_i$.

The second step in the mimetic technique is to equip the spaces of discrete pressures and velocities with scalar products. We denote the vector space of cell-centered pressures by $Q^d$. The dimension of $Q^d$ equals the number of mesh cells $N_p$. The scalar product on the vector space $Q^d$ is given by

$$[p^d, q^d]_{Q^d} = \sum_{i=1}^{N_p} |e_i| p^d_q^d e^d_i, \quad \forall p^d, q^d \in Q^d, \tag{3.1}$$

where $|e_i|$ denotes the area of cell $e_i$ and $p^d_i, q^d_i$ are cell-centered pressure components.

It is easy to see that the vector space $Q^d$ is isometric to the MFE space $W^h$ in (2.8). Indeed, for any $p^h \in W^h$, there exists a unique $p^d = (p^d_1, p^d_2, \cdots, p^d_{N_p})^T \in Q^d$, such that $p^h = \sum_{i=1}^{N_p} p^d_i \psi^h_i$ and

$$(p^h, q^h) = [p^d, q^d]_{Q^d}.$$ 

Note that the discrete MFD pressure variable, $p^d_i$, corresponds to the value of the MFE pressure function at the cell-center, $p^h(c_i)$.

We denote the vector space of edge-based velocities by $X^d$. The dimension of $X^d$ equals the number of interior mesh edges $N_e$. The scalar product on $X^d$ is given by

$$[u^d, v^d]_{X^d} = \sum_{e \in T_h} [u^d, v^d]_{X^d_{e}}, \tag{3.2}$$
where \([u^d, v^d]|_{X^d,e}\) is a scalar product over cell \(e\) involving only the normal velocity components on cell edges. Recall that a velocity vector can be recovered from two orthogonal projections on any two non-collinear vectors. Since the mesh cell is convex, any pair of normal vectors to edges with a common point satisfy the above requirement. The orthogonal projections are exactly the degrees of freedom associated with cell edges. As shown in Fig. 3.1, four recovered velocity vectors can be associated with the four vertices of the quadrilateral. For example, velocity \(v^d_1\) is recovered from its projections onto the normal vectors \(n_1\) and \(n_2\). For a general quadrilateral \(e\), we denote by \(v^d_{r_j}\) the velocity recovered at \(j\)-th vertex \(r_j\), \(j = 1, 2, 3, 4\). Then, the cell-based scalar product is given by

\[
[u^d, v^d]|_{X^d,e} = \frac{1}{2} \sum_{j=1}^{4} |T_j| K^{-1}(r_j) u^d(r_j) \cdot v^d(r_j),
\]

(3.3)

where \(|T_j|\) is the area of the triangle with vertices \(r_{j-1}, r_j\) and \(r_{j+1}\) (see Fig. 2.2 and Fig. 3.1). For example, triangles \(T_1\) and \(T_4\) are the shaded triangles in Fig. 3.1. Note that (3.3) is indeed an inner product, since \(K\) is a symmetric and positive definite tensor and

\[
[v^d, v^d]|_{X^d} \geq C||v^d||^2,
\]

(3.4)

where \(||| \cdot |||\) is the Euclidean vector norm.

![Fig. 3.1. Recovered vectors \(v_1, v_4\) and triangles \(T_1, T_4\).](image)

The vector space \(X^d\) is isomorphic to the MFE space \(V^h\) in (2.8), since both spaces have the same definitions of degrees of freedom. In particular, for any \(v^h \in V^h\), there exists a unique \(v^d = (v^d_1, v^d_2, \cdots, v^d_{N_e})^T \in X^d\) such that \(v^h = \sum_{i=1}^{N_e} v^d_i \phi_i^h\). Note that the discrete MFD velocity variable, \(v^d_i\), corresponds to the MFE normal velocity component, \(v^h_i \cdot n_i\), on edge \(\ell_i\).

The third step in the mimetic technique is to derive a discrete approximation to the divergence operator, \(DIV : X^d \rightarrow Q^d\), which we shall refer to as the prime operator. For a cell \(e\), the Gauss divergence theorem gives

\[
DIV u^d|_e = \frac{1}{|e|} \left( u^d_1|\ell_1| + u^d_2|\ell_2| + u^d_3|\ell_3| + u^d_4|\ell_4| \right)
\]

(3.5)

where \(u^d_1, \ldots, u^d_4\) are the normal velocity components on element \(e\) and the normal vectors are oriented as shown in Fig. 2.2.
The fourth step in the mimetic technique is to derive a discrete flux operator \( \mathcal{G} \) (for the continuous operator \(-\mathbf{K}\mathbf{grad}\)) adjoint to the discrete divergence operator \( \text{DIV} \) with respect to scalar products (3.1) and (3.2), i.e.

\[
[\text{DIV} \mathbf{u}^d, \mathbf{p}^d]_{Q^d} \equiv [\mathbf{u}^d, \mathcal{G}\mathbf{p}^d]_{X^d}, \quad \forall \mathbf{u}^d \in X^d, \quad \forall \mathbf{p}^d \in Q^d.
\]

To derive the explicit formula for \( \mathcal{G} \), we consider an auxiliary scalar product \( <\cdot, \cdot> \) and relate it to scalar products (3.1) and (3.2). Denote by \( <\cdot, \cdot> \) the standard vector dot product. Then

\[
[p^d, q^d]_{Q^d} = <Dp^d, q^d>, \quad \text{and} \quad [\mathbf{u}^d, \mathbf{v}^d]_{X^d} = <\mathcal{M}\mathbf{u}^d, \mathbf{v}^d>,
\]

where \( D \) is a diagonal matrix, \( D = \text{diag}([|e_1|, \ldots, |e_{N_p}|]) \), and \( \mathcal{M} \) is a sparse symmetric mass matrix with a 5-point stencil. Restricted to a cell, this stencil connects edge-based unknowns if and only if the corresponding edges have a common point.

Combining the last two formulae, we get

\[
[u^d, \text{DIV}^* p^d]_{X^d} = <u^d, \mathcal{M} \text{DIV}^* p^d> = [\text{DIV} u^d, p^d]_{Q^d}
\]

\[
= <u^d, \text{DIV}^t D p^d>, \quad \forall u^d \in X^d, \quad \forall p^d \in Q^d,
\]

where \( \text{DIV}^t \) is the adjoint of \( \text{DIV} \) with respect to the auxiliary scalar product. Therefore,

\[
\mathcal{G} = \mathcal{M}^{-1} \text{DIV}^t D. \quad (3.6)
\]

The mimetic finite difference method approximating first-order system (1.1) may be summarized as follows

\[
\mathbf{u}^d = \mathcal{G} \mathbf{p}^d, \quad \text{DIV} \mathbf{u}^d = f^d, \quad (3.7)
\]

where \( f^d = (f_1^d, \ldots, f_N^d) \), and entry \( f_i^d \) is the integral average of \( f \) over cell \( e_i \).

The basic tool for the error analysis of the discrete solution \((\mathbf{u}^d, \mathbf{p}^d) \in X^d \times Q^d\) is based on following transformation. Multiplying the first equation in (3.7) by \( \mathcal{M}\mathbf{v}^d \) and the second one by \( D\mathbf{q}^d \), we get

\[
[u^d, \mathbf{v}^d]_{X^d} - [p^d, \text{DIV} \mathbf{v}^d]_{Q^d} = 0,
\]

\[
[p^d, \text{DIV} \mathbf{u}^d]_{Q^d} = [f^d, q^d]_{Q^d}, \quad \forall (\mathbf{v}^d, \mathbf{q}^d) \in X^d \times Q^d. \quad (3.8)
\]

Using the isomorphism between finite element space \( \mathbf{V}^h \times \mathbf{W}^h \) and vector space \( X^d \times Q^d \), we define finite element functions \( p^h, q^h, f^h, \mathbf{u}^h \) and \( \mathbf{v}^h \) corresponding to vectors \( p^d, q^d, f^d, \mathbf{u}^d \) and \( \mathbf{v}^d \), respectively. Then,

\[
[p^d, \text{DIV} \mathbf{v}^d]_{Q^d} = (p^h, \text{div} \mathbf{v}^h) \quad \text{and} \quad [q^d, \text{DIV} \mathbf{u}^d]_{Q^d} = (q^h, \text{div} \mathbf{u}^h).
\]

The definition of \( f^d \) implies that

\[
[f^d, q^d]_{Q^d} = (f^h, q^h) = (f, q^h).
\]

Finally, by introducing the quadrature rule

\[
(\mathbf{K}^{-1}\mathbf{u}^h, \mathbf{v}^h)_h \equiv [\mathbf{u}^d, \mathbf{v}^d]_{X^d}, \quad (3.9)
\]

we reduce problem (3.7) to the finite element problem (2.10).
The scalar product in the space of velocities given by (3.3) is obviously not unique. In the context of MFE methods, it is a quadrature rule for numerical integration of \((K^{-1}u^h, v^h)\):

\[
(K^{-1}u^h, v^h)_{h,e} = \frac{1}{2} \sum_{j=1}^{4} |T_j| K^{-1}(r_j)u^h(r_j) \cdot v^h(r_j),
\]

(3.10)

where \(u^h(r_j)\) is the recovered velocity at vertex \(r_j\). In context of MFE methods, we shall refer to (3.10) as the MFD quadrature rule. The global scalar product is obtained by summing over quadrilaterals, i.e.

\[
(K^{-1}u^h, v^h)_h = \sum_{e \in T_h} (K^{-1}u^h, v^h)_{h,e}.
\]

(3.11)

Note that (3.4) implies that there exists a constant \(C_0 > 0\) such that

\[
(K^{-1}v^h, v^h)_h \geq C_0 \|v^h\|^2 \quad \forall v^h \in V^h.
\]

(3.12)

It was shown in [4] that the element quadrature rule (3.10) is exact for any constant vector \(u^h\), constant tensor \(K\), and \(v^h \in V^h\).

4. Superconvergence estimates for the velocity. We begin by recalling the mixed projection operator \(\Pi : H^1(\Omega) \times H^1(\Omega) \rightarrow V^h\) satisfying

\[
(\text{div}(\Pi \mathbf{v} - \mathbf{v}), w) = 0 \quad \forall w \in W^h.
\]

(4.1)

The operator \(\Pi\) is defined locally on each element \(e\) by

\[
\hat{\Pi} \mathbf{v} = \hat{\Pi} \mathbf{v},
\]

where \(\hat{\Pi} : H^1(\hat{\mathbf{e}}) \times H^1(\hat{\mathbf{e}}) \rightarrow \hat{V}(\hat{\mathbf{e}})\) is the reference element projection operator satisfying

\[
\int_{\hat{\mathbf{e}}} (\hat{\Pi} \mathbf{v} - \mathbf{v}) \cdot \hat{n} = 0, \quad i = 1, 2, 3, 4.
\]

(4.2)

The approximation properties of \(\Pi\) have been established in [25, 26]:

\[
\|\Pi \mathbf{v}\|_{\text{div}} \leq C\|\mathbf{v}\|_1, \quad (4.3)
\]

\[
\|\Pi \mathbf{v} - \mathbf{v}\| \leq Ch\|\mathbf{v}\|_1, \quad (4.4)
\]

\[
\|\text{div}(\Pi \mathbf{v} - \mathbf{v})\| \leq Ch\|\mathbf{v}\|_2. \quad (4.5)
\]

The following lemma gives several approximation properties of \(\hat{\Pi}\) which will be used in the analysis.

**Lemma 4.1.** The operator \(\hat{\Pi}\) defined in (4.2) satisfies, for any \(\hat{\mathbf{v}} = (\hat{\mathbf{v}}_1, \hat{\mathbf{v}}_2)\) in \(H^1(\hat{\mathbf{e}}) \times H^1(\hat{\mathbf{e}})\), the following:

\[
\int_{\hat{\mathbf{e}}} \frac{\partial}{\partial x} (\hat{\Pi} \mathbf{v} - \mathbf{v})_1 \, d\hat{x} d\hat{y} = 0, \quad \int_{\hat{\mathbf{e}}} \frac{\partial}{\partial y} (\hat{\Pi} \mathbf{v} - \mathbf{v})_2 \, d\hat{x} d\hat{y} = 0, \quad (4.6)
\]

\[
\left\| \frac{\partial}{\partial x} (\hat{\Pi} \mathbf{v})_1 \right\|_{\hat{\mathbf{e}}} \leq C \left\| \frac{\partial}{\partial x} \hat{\mathbf{v}}_1 \right\|_{\hat{\mathbf{e}}}, \quad \left\| \frac{\partial}{\partial y} (\hat{\Pi} \mathbf{v})_2 \right\|_{\hat{\mathbf{e}}} \leq C \left\| \frac{\partial}{\partial y} \hat{\mathbf{v}}_2 \right\|_{\hat{\mathbf{e}}}, \quad (4.7)
\]

\[
\|\hat{\Pi} \mathbf{v}\|_{1,\hat{\mathbf{e}}} \leq C \|\hat{\mathbf{v}}\|_{1,\hat{\mathbf{e}}}. \quad (4.8)
\]
Proof: The identities in (4.6) follow easily from the definition (4.2). In particular, writing (4.2) for the two vertical edges gives
\[ \int_{0}^{1} (\hat{\Pi} \hat{v} - \hat{v})_{1} (0, \hat{y}) d\hat{y} = 0, \]
\[ \int_{0}^{1} (\hat{\Pi} \hat{v} - \hat{v})_{1} (1, \hat{y}) d\hat{y} = 0. \]
Subtracting the above equations and applying the fundamental theorem of calculus implies the first identity in (4.6). The proof of the second identity is similar. Note that (4.6) means that \( \partial_{x} (\hat{\Pi} \hat{v})_{1} \) and \( \partial_{y} (\hat{\Pi} \hat{v})_{2} \) are the \( L^{2} \)-orthogonal projections of \( \partial_{x} \hat{v}_{1} \) and \( \partial_{y} \hat{v}_{2} \), respectively, onto the space of constants, which implies (4.7). Finally, it is easy to see that (4.2) implies
\[ \| \hat{\Pi} \hat{v} \| \leq C \| \hat{v} \| \|_{1, \hat{e}}, \]
which, combined with (4.7), gives (4.8).

We also make use of the \( L^{2} \)-projection operator \( P_{h} : W \rightarrow W^{h} \), such that for \( p \in W \),
\[ (P_{h} p - p, w) = 0 \quad \forall w \in W^{h}. \] (4.9)
Denote the quadrature error by
\[ \sigma(q, v) \equiv (q, v) - (q, v)_{h}. \] (4.10)
The variational formulation (2.1) and the discrete problem (2.10) give rise to the error equations
\[ (K^{-1}(\Pi u - u^{h}), v^{h})_{h} = (P_{h} p - p^{h}, \text{div} v^{h}) \]
\[ + (K^{-1}(\Pi u - u), v^{h}) - \sigma(K^{-1}\Pi u, v^{h}), \] (4.11)
where we used (4.9) and (4.1) in the first and the second equation, respectively. We note that, using (2.9), the second equation in (4.11) gives
\[ 0 = (\text{div} (\Pi u - u^{h}), w^{h})_{e} = (\hat{\text{div}} (\hat{\Pi} \hat{u} - \hat{u}^{h}), \hat{w}^{h})_{e} \quad \forall w^{h} \in W_{h}. \]
Since \( \hat{\text{div}} \hat{v}^{h} = \hat{W}_{h} \), taking \( \hat{w}^{h} = \hat{\text{div}} (\hat{\Pi} \hat{u} - \hat{u}^{h}) \) implies that \( \hat{\text{div}} (\hat{\Pi} \hat{u} - \hat{u}^{h}) = 0 \) and therefore, by (2.9),
\[ \text{div} (\Pi u - u^{h}) = 0. \] (4.12)
Taking \( v^{h} = \Pi u - u^{h} \in V^{h} \) and \( u^{h} = P_{h} p - p^{h} \) in (4.11) gives
\[ (K^{-1}(\Pi u - u^{h}), \Pi u - u^{h})_{h} = (K^{-1}(\Pi u - u), \Pi u - u^{h}) - \sigma(K^{-1}\Pi u, \Pi u - u^{h}) \] (4.13)
The estimate for the first term on the right hand side of (4.13) follows from Theorem 5.1 in [13] and (4.12):
\[ (K^{-1}(\Pi u - u), \Pi u - u^{h}) \leq C h^{2} (\| u \|_{2} \| \Pi u - u^{h} \| + \| u \|_{1} \| \text{div} (\Pi u - u^{h}) \|) \] (4.14)
\[ = C h^{2} \| u \|_{2} \| \Pi u - u^{h} \|, \]
The second term on the right hand side of (4.13) can be bounded using Lemma 4.3 below,

$$|\sigma(K^{-1}\Pi u, \Pi u - u^h)| \leq C h^2 \|u\|_2 \|\Pi u - u^h\|.$$  \hspace{1cm} (4.15)

Combining (4.14), (4.15) and (3.12), we obtain the following superconvergence result.

**Theorem 4.2.** Let $K^{-1} \in W^{2,\infty}(\Omega)$. For the velocity $u^h$ of the mixed finite element method (2.1), on $h^2$-uniform quadrilateral grids, there exists a positive constant $C$ independent of $h$ such that

$$\|\Pi u - u^h\| \leq C h^2 \|u\|_2.$$ \hspace{1cm} (4.16)

We now proceed to prove estimate (4.15).

**Lemma 4.3.** Let $v \in V^h$ and $K^{-1} \in W^{2,\infty}(\Omega)$. There exists a positive constant $C$ independent of $h$ such that

$$|\sigma(K^{-1}\Pi u, v)| \leq C h^2 (\|u\|_2 \|v\| + \|u\|_1 \|\text{div} \ v\|).$$ \hspace{1cm} (4.17)

**Proof:** For an element $e \in T^h$, we define the error

$$\sigma_e(K^{-1}\Pi u, v) = \int_e K^{-1}\Pi u \cdot v \, dx - (K^{-1}\Pi u, v)_{e,e}.$$ \hspace{1cm} (4.18)

With (3.10), the second term on the right hand side of (4.18) can be written as

$$(K^{-1}\Pi u, v)_{e,e} = \frac{1}{2} \sum_{j=1}^4 |T_j| \frac{1}{J_e} K^{-1} (r_j) \Pi u(r_j) \cdot v(r_j)$$

$$= \frac{1}{2} \sum_{j=1}^4 |T_j| \frac{1}{J_e} DF_e \hat{u} \hat{v}(r_j) \cdot \left( \frac{1}{J_e} DF_e \hat{v}(r_j) \right)$$

$$= \frac{1}{2} \sum_{j=1}^4 \frac{|T_j|}{J_e(\hat{r}_j)} \frac{1}{J_e(\hat{r}_j)} DF^T_e(\hat{r}_j) K^{-1}(\hat{r}_j) DF_e(\hat{r}_j) \hat{u}(\hat{r}_j) \cdot \hat{v}(\hat{r}_j)$$

$$= \frac{1}{2} \sum_{j=1}^4 B_e(\hat{r}_j) \hat{u}(\hat{r}_j) \cdot \hat{v}(\hat{r}_j)$$

$$\equiv (B_e, \hat{u}, \hat{v})_T,$$

where the subscript $T$ denotes the trapezoidal rule on element $e$ and we define $B_e = \frac{1}{J_e} DF^T_e K^{-1} DF_e$. Here we used (2.6) to conclude that $\frac{|T_j|}{J_e(\hat{r}_j)} = 1/2$. Considering the first term on the right hand side of (4.18), we obtain

$$\int_e K^{-1}\Pi u \cdot v \, dx = \int_{\hat{e}} \hat{K}^{-1} \frac{1}{J_e} DF_e \hat{u} \cdot \frac{1}{J_e} DF_e \hat{v} J_e \, d\hat{x}$$

$$= \int_{\hat{e}} \frac{1}{J_e} DF^T_e \hat{K}^{-1} DF_e \hat{u} \cdot \hat{v} \, d\hat{x}$$

$$= \int_{\hat{e}} B_e \hat{u} \cdot \hat{v} \, d\hat{x}.$$ \hspace{1cm} (4.20)
Substituting (4.19) and (4.20) into (4.18), we obtain
\[
\sigma_\varepsilon(K^{-1}\Pi u, v) = \int_{\hat{\mathcal{E}}} B_\varepsilon \hat{\Pi} \hat{u} \cdot \hat{\nu} \, d\hat{x} - (B_\varepsilon \hat{\Pi} \hat{u}, \hat{\nu})_T \equiv \sigma_\varepsilon(B_\varepsilon \hat{\Pi} \hat{u}, \hat{\nu}). \tag{4.21}
\]
Hereafter we shall omit the subscripts \(\varepsilon\) and \(\hat{\varepsilon}\). Let
\[
E(f) \equiv \int_{\hat{\mathcal{E}}} f(\hat{x}, \hat{y}) d\hat{x} d\hat{y} - (f)_T
\]
be the error of the trapezoidal rule for integrating a function \(f(\hat{x}, \hat{y})\) on \(\hat{\mathcal{E}}\). Then,
\[
\sigma(B\hat{\Pi} \hat{u}, \hat{\nu}) = E((B\hat{\Pi} \hat{u})_1 \hat{v}_1) + E((B\hat{\Pi} \hat{u})_2 \hat{v}_2). \tag{4.22}
\]
We next bound the first term on the right in (4.22). The argument for the bound on the second term is similar.

Using the trapezoidal rule error representation from Lemma A.1 based on the Peano Kernel Theorem (see [23, p. 142, Theorem 5.2-3]), we write
\[
E((B\hat{\Pi} \hat{u})_1 \hat{v}_1) = \int_{0}^{1} \int_{0}^{1} \phi(\hat{x}) \frac{\partial^2}{\partial \hat{x}^2}((B\hat{\Pi} \hat{u})_1(\hat{x}, 0) d\hat{x} d\hat{y}
+ \int_{0}^{1} \int_{0}^{1} \phi(\hat{y}) \frac{\partial^2}{\partial \hat{y}^2}(B\hat{\Pi} \hat{u})_1(0, \hat{y}) \hat{v}_1(0, \hat{y}) d\hat{x} d\hat{y}
\equiv (I) + (II), \tag{4.23}
\]
where \(\phi(t) = t(t - 1)/2\). Denote by \(B_{11}, B_{12}, B_{21},\) and \(B_{22}\) the components of the tensor \(B\). Since \(\hat{v}_1(0, \hat{y})\) is constant in \(\hat{y}\), the second term in (4.23) is
\[
(II) = \int_{0}^{1} \int_{0}^{1} \phi(\hat{y}) \frac{\partial^2}{\partial \hat{y}^2} B_{11}(0, \hat{y}) (\hat{\Pi} \hat{u})_1(0, \hat{y}) \hat{v}_1(0, \hat{y}) d\hat{x} d\hat{y}
+ \int_{0}^{1} \int_{0}^{1} \phi(\hat{y}) \frac{\partial^2}{\partial \hat{y}^2} B_{12}(0, \hat{y}) (\hat{\Pi} \hat{u})_2(0, \hat{y}) \hat{v}_1(0, \hat{y}) d\hat{x} d\hat{y}
+ 2 \int_{0}^{1} \int_{0}^{1} \phi(\hat{y}) \frac{\partial}{\partial \hat{y}} B_{12}(0, \hat{y}) (\hat{\Pi} \hat{u})_2(0, \hat{y}) \hat{v}_1(0, \hat{y}) d\hat{x} d\hat{y}
\equiv (II)_1 + (II)_2 + (II)_3. \tag{4.24}
\]
Using (4.8), for the first two terms on the right we have
\[
||(II)_1| + |(II)_2| \leq C|B|_{2, \infty, \hat{\varepsilon}} \hat{\Pi} \|1, \hat{\varepsilon}\| \|\hat{\nu}_1\|_\hat{\varepsilon}.
\]
Since \(\frac{\partial}{\partial \hat{y}} (\hat{\Pi} \hat{u})_2\) is a constant, we rewrite the last term in (4.24) as
\[
(II)_3 = 2 \int_{0}^{1} \int_{0}^{1} \phi(\hat{y}) \frac{\partial}{\partial \hat{y}} B_{12}(0, \hat{y}) \frac{\partial}{\partial \hat{y}} (\hat{\Pi} \hat{u})_2(\hat{x}, \hat{y}) \hat{v}_1(0, \hat{y}) d\hat{x} d\hat{y}
\leq C|B|_{1, \infty, \hat{\varepsilon}} \|\frac{\partial}{\partial \hat{y}} (\hat{\Pi} \hat{u})_2\|_\hat{\varepsilon} \|\hat{v}_1\|_\hat{\varepsilon} \leq C|B|_{1, \infty, \hat{\varepsilon}} \|\hat{u}_1\|_\hat{\varepsilon} \|\hat{v}_1\|_\hat{\varepsilon},
\]
using (4.7). A combination of the last two bounds implies that
\[
|((II)| \leq C(|B|_{2, \infty, \hat{\varepsilon}} \|\hat{u}_1\|_\hat{\varepsilon} + |B|_{1, \infty, \hat{\varepsilon}} \|\hat{u}_1\|_\hat{\varepsilon}) \|\hat{v}_1\|_\hat{\varepsilon}. \tag{4.25}
\]
The first term in the error representation (4.23) is

\[
(I) = \int_0^1 \int_0^1 \phi(x) \frac{\partial^2}{\partial x^2} (B \hat{u})_1(x,0) \hat{v}_1(x,0) \, dx \, dy + 2 \int_0^1 \int_0^1 \phi(x) \frac{\partial}{\partial x} (B \hat{u})_1(x,0) \frac{\partial}{\partial x} \hat{v}_1(x,0) \, dx \, dy = (I)_1 + (I)_2.
\] (4.26)

The first term on the right can be bounded in a way similar to (II):

\[
|(I)_1| \leq C(|B|_{2,\infty,\varepsilon} \|\hat{u}\|_{1,\varepsilon} + |B|_{1,\infty,\varepsilon} |\hat{u}|_{1,\varepsilon}) \|\hat{v}_1\|_{\varepsilon}.
\] (4.27)

We rewrite the second term on the right in (4.26) as

\[
\frac{1}{2} (I)_2 = \int_0^1 \int_0^1 \phi(x) \left( \frac{\partial}{\partial x} (B \hat{u})_1(x,0) - \frac{\partial}{\partial x} (B \hat{u})_1(x,y) \right) \frac{\partial}{\partial x} \hat{v}_1(x,0) \, dx \, dy + \int_0^1 \int_0^1 \phi(x) \frac{\partial}{\partial x} (B \hat{u})_1(x,y) \frac{\partial}{\partial x} \hat{v}_1(x,0) \, dx \, dy = (I)_{2,1} + (I)_{2,2}.
\] (4.28)

To estimate the first term in (4.28), we write

\[
\frac{\partial}{\partial x} (B \hat{u})_1(x,y) - \frac{\partial}{\partial x} (B \hat{u})_1(x,0) = \int_0^y \frac{\partial^2}{\partial x \partial y} (B \hat{u})_1(x,t) \, dt.
\]

This allows us to bound the first term in (4.28) in a way similar to bounds (4.25) and (4.27):

\[
|(I)_{2,1}| \leq C(|B|_{2,\infty,\varepsilon} \|\hat{u}\|_{1,\varepsilon} + |B|_{1,\infty,\varepsilon} |\hat{u}|_{1,\varepsilon}) \|\hat{v}_1\|_{\varepsilon}.
\] (4.29)

The second term on the right in (4.28) can be rewritten as

\[
(I)_{2,2} = \int_0^1 \int_0^1 \phi(x) \frac{\partial}{\partial x} (B(\hat{u} - \hat{u}))(x,y) \frac{\partial}{\partial x} \hat{v}_1(x,y) \, dx \, dy + \int_0^1 \int_0^1 \phi(x) \frac{\partial}{\partial x} (B \hat{u})_1(x,y) \frac{\partial}{\partial x} \hat{v}_1(x,y) \, dx \, dy = (I)_{2,2,1} + (I)_{2,2,2},
\] (4.30)

where we used that \( \frac{\partial}{\partial x} \hat{v}_1(x,0) = \frac{\partial}{\partial y} \hat{v}_1(x,y) \) on \( \varepsilon \), since \( \hat{v}_1 \) is constant in \( \varepsilon \).

To estimate the second term in (4.30), we use the identity

\[
\frac{\partial}{\partial x} \hat{v}_1 = - \frac{\partial}{\partial y} \hat{v}_2 + \text{div} \hat{v}.
\] (4.31)

We rewrite (I)_{2,2,2} as

\[
(I)_{2,2,2} = - \int_0^1 \int_0^1 \phi(x) \frac{\partial}{\partial x} (B \hat{u})_1 \frac{\partial}{\partial y} \hat{v}_2 \, dx \, dy + \int_0^1 \int_0^1 \phi(x) \frac{\partial}{\partial x} (B \hat{u})_1 \text{div} \hat{v} \, dx \, dy
\]

\[
= \left[ \hat{t} - \int_{\hat{t}}^1 \phi(x) \frac{\partial}{\partial x} (B \hat{u})_1 \hat{v}_2 \, dx \right] + \int_0^1 \int_0^1 \phi(x) \frac{\partial^2}{\partial x \partial y} (B \hat{u})_1 \hat{v}_2 \, dx \, dy
\]

\[
+ \int_0^1 \int_0^1 \phi(x) \frac{\partial}{\partial x} (B \hat{u})_1 \text{div} \hat{v} \, dx \, dy.
\] (4.32)
Clearly, the last two terms can be bounded by

\[ C(\|B\tilde{u}\|_{1,\tilde{\varepsilon}}\|\hat{v}_2\|\tilde{\varepsilon} + \|B\tilde{u}\|_{1,\varepsilon}\|\hat{v}\|\varepsilon) \]  
(4.33)

We postpone the estimate of the edge integrals in (4.32) for later.

To bound the first term on the right in (4.30), we have

\[
(I)_{2.2.1} = \int_0^1 \int_0^1 \phi(\hat{x}) \frac{\partial}{\partial \hat{x}} B_{11}(\hat{x}, \hat{y}) (\hat{\Pi}u - \tilde{u})_1(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} \\
+ \int_0^1 \int_0^1 \phi(\hat{x}) B_{11}(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} (\hat{\Pi}u - \tilde{u})_1(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} \\
+ \int_0^1 \int_0^1 \phi(\hat{x}) B_{12}(\hat{x}, \hat{y})(\hat{\Pi}u - \tilde{u})_2(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} \\
+ \int_0^1 \int_0^1 \phi(\hat{x}) B_{12}(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} (\hat{\Pi}u - \tilde{u})_2(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} \\
\equiv (I)_{2.2.1.1} + (I)_{2.2.1.2} + (I)_{2.2.1.3} + (I)_{2.2.1.4}
\]  
(4.34)

Since \(\hat{\Pi}u\) is exact for constants, using the Bramble-Hilbert lemma and the inverse inequality, we can bound the first and the third terms in (4.34) as

\[ |(I)_{2.2.1.1}| + |(I)_{2.2.1.3}| \leq C \|B\|_{1,\infty,\tilde{\varepsilon}} \|\hat{u}\|_{1,\varepsilon} \|\hat{v}_1\|\varepsilon. \]  
(4.35)

For the second term in (4.34), a Taylor expansion of \(B_{11}\) about the any fixed point \((\hat{x}_0, \hat{y}_0) \in \tilde{\varepsilon}\) gives

\[
(I)_{2.2.1.2} = \int_0^1 \int_0^1 \phi(\hat{x}) B_{11}(\hat{x}_0, \hat{y}_0) \frac{\partial}{\partial \hat{x}} (\hat{\Pi}u - \tilde{u})_1(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} + R,
\]  
(4.36)

where

\[ |R| \leq C \|B\|_{1,\infty,\tilde{\varepsilon}} \|\hat{u}\|_{1,\varepsilon} \|\hat{v}_1\|\varepsilon, \]  
(4.37)

using (4.7) for the last inequality. To bound the first term on the right in (4.36), we note that

\[ (\phi^2)''(\hat{x}) = 6\phi(\hat{x}) + \frac{1}{2}, \quad (\phi^2)'(0) = (\phi^2)'(1) = 0. \]

Therefore, using (4.6), we have

\[
\int_0^1 \int_0^1 \phi(\hat{x}) B_{11}(\hat{x}_0, \hat{y}_0) \frac{\partial}{\partial \hat{x}} (\hat{\Pi}u - \tilde{u})_1(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} \\
= \frac{1}{6} \int_0^1 \int_0^1 \frac{\partial^2}{\partial \hat{x}^2} (\phi^2)(\hat{x}) B_{11}(\hat{x}_0, \hat{y}_0) \frac{\partial}{\partial \hat{x}} (\hat{\Pi}u - \tilde{u})_1(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} \\
= -\frac{1}{6} \int_0^1 \int_0^1 \frac{\partial}{\partial \hat{x}} (\phi^2)(\hat{x}) B_{11}(\hat{x}_0, \hat{y}_0) \frac{\partial^2}{\partial \hat{x}^2} (\hat{\Pi}u - \tilde{u})_1(\hat{x}, \hat{y}) \frac{\partial}{\partial \hat{x}} \hat{v}_1(\hat{x}, \hat{y}) \, d\hat{x} \, d\hat{y} \\
\leq C \|B\|_{1,\infty,\tilde{\varepsilon}} \|\hat{u}\|_{1,\varepsilon} \|\hat{v}_1\|\varepsilon.
\]  
(4.38)

A combination of (4.36)–(4.38) gives

\[ |(I)_{2.2.1.2}| \leq C(\|B\|_{1,\infty,\tilde{\varepsilon}} \|\hat{u}\|_{1,\varepsilon} + \|B\|_{\infty,\tilde{\varepsilon}} \|\hat{u}\|_{2,\varepsilon}) \|\hat{v}_1\|\varepsilon. \]  
(4.39)
Combining (4.23)–(4.41), we obtain

\[ (I)_{2,2,1,4} = \int_{\hat{t}_i}^{\hat{t}_f} \left( \int_0^1 \frac{\partial}{\partial \hat{x}} B_{12} \frac{\partial}{\partial \hat{y}} \hat{u}_2 \hat{v}_2 d\hat{x} d\hat{y} \right) \]

\[ = \int_{\hat{t}_i}^{\hat{t}_f} \left( \int_0^1 \frac{\partial}{\partial \hat{y}} \left( B_{12} \frac{\partial}{\partial \hat{x}} \hat{u}_2 \right) \hat{v}_2 d\hat{x} d\hat{y} \right) \]

\[ - \int_{\hat{t}_i}^{\hat{t}_f} \int_0^1 \phi(\hat{x}) B_{12} \frac{\partial}{\partial \hat{x}} \hat{u}_2 \hat{v}_2 d\hat{x} d\hat{y}. \]

The last two terms above are bounded by

\[ C \left( \|B\|_{1,\infty,\hat{e}} \|\hat{u}\|_{1,\hat{e}} + \|B\|_{1,\infty,\hat{e}} \|\hat{u}\|_{1,\hat{e}} + \|B\|_{\infty,\hat{e}} \|\hat{u}\|_{1,\hat{e}} \|\nabla \hat{v}\|_{\hat{e}} \right). \]

Combining (4.23)–(4.41), we obtain

\[ E((B\hat{u})_1 \hat{v}_1) = T_1 + T_2 + T_3, \]

where

\[ |T_1| \leq C \left( \|B\|_{2,\infty,\hat{e}} \|\hat{u}\|_{1,\hat{e}} + \|B\|_{1,\infty,\hat{e}} \|\hat{u}\|_{1,\hat{e}} + \|B\|_{\infty,\hat{e}} \|\hat{u}\|_{1,\hat{e}} \|\nabla \hat{v}\|_{\hat{e}} \right), \]

\[ T_2 = \int_{\hat{t}_i}^{\hat{t}_f} \phi(\hat{x}) \frac{\partial}{\partial \hat{x}} (B\hat{u})_1 (\hat{x}, \hat{y}) \hat{v}_2(\hat{x}, \hat{y}) d\hat{x}, \]

and

\[ T_3 = \int_{\hat{t}_i}^{\hat{t}_f} \int_0^1 \phi(\hat{x}) B_{12} \frac{\partial}{\partial \hat{x}} \hat{u}_2(\hat{x}, \hat{y}) \hat{v}_2(\hat{x}, \hat{y}) d\hat{x}. \]

Using Lemma 4.4 below, \( T_1 \) can be bounded as follows:

\[ |T_1| \leq C \left( \|K^{-1}\|_{2,\infty,\hat{e}} \|u\|_{1,\hat{e}} + h \|K^{-1}\|_{1,\infty,\hat{e}} \|u\|_{1,\hat{e}} + \|K^{-1}\|_{\infty,\hat{e}} h^2 \|u\|_{2,\hat{e}} \|v\|_{\hat{e}} \right)

\[ + (h \|K^{-1}\|_{1,\infty,\hat{e}} \|u\|_{1,\hat{e}} + \|K^{-1}\|_{\infty,\hat{e}} \|u\|_{1,\hat{e}}) h \|\nabla v\|_{\hat{e}} \right). \]

\[ \leq C h^2 (\|K^{-1}\|_{2,\infty,\hat{e}} \|u\|_{2,\hat{e}} \|v\|_{\hat{e}} + \|K^{-1}\|_{1,\infty,\hat{e}} \|u\|_{1,\hat{e}} \|\nabla v\|_{\hat{e}}), \]

using that \( |\hat{u}|_{j,\hat{e}} \leq Ch \|u\|_{j,\hat{e}} \) and \( \|\nabla \hat{v}\|_{\hat{e}} \leq C h \|v\|_{\hat{e}} \) (see [13, Lemma 5.5]).

The term \( \sum_{\hat{e}} T_2 \) is treated in Lemma 4.5 below.

Finally, term \( T_3 \) in (4.42) can be rewritten as

\[ T_3 = \int_{\hat{t}_i}^{\hat{t}_f} \int_0^1 \phi(\hat{s}) B_{12} (\hat{s}, \hat{y}) \frac{\partial}{\partial \hat{s}} (\hat{u} \cdot \hat{n}_k) \hat{v} \cdot \hat{n}_k d\hat{s}. \]

A similar term appears in the proof of Theorem 5.1 in [13]. Following the argument there, it can be shown that

\[ \left| \sum_{\hat{e}} T_3 \right| \leq C \sum_{\hat{e}} h^2 \|u\|_{2,\hat{e}} \|v\|_{\hat{e}}. \]
A combination of estimates (4.42), (4.45), (4.48), and (4.46) implies that
\[
\sum_{e} |E((B\hat{H}\hat{u})_1 \hat{v}_1)| \leq C h^2 (\|u\|_2 \|v\| + \|u\|_1 \|\text{div} \, v\|).
\]
The argument for \(E((B\hat{H}\hat{u})_2 \hat{v}_2)\) is analogous. This completes the proof of the lemma. \(\square\)

We next give the proofs of the two auxiliary lemmas used in the above argument.

**Lemma 4.4.** If \(K^{-1} \in W^{2,\infty}(\Omega)\), then for all \(e \in T_h\) there exists a positive constant \(C\) independent of \(h\) such that
\[
|B|_{s,\infty,\hat{e}} \leq C h^s \|K\|_{s,\infty,\hat{e}}, \quad s = 0, 1, 2.
\]

**Proof:** First, for a quasi-uniform mesh, we have
\[
c_1 h \leq \|DF\|_{\infty,\hat{e}} \leq c_2 h, \quad c_3 h^2 \leq \|J\|_{\infty,\hat{e}} \leq c_4 h^2
\]
with some positive constants \(c_1-c_4\). This implies that
\[
\|B\|_{\infty,\hat{e}} \leq C \|\hat{K}^{-1}\|_{\infty,\hat{e}}. \tag{4.47}
\]

Second, for an \(h^2\)-uniform mesh, we have additional estimates. Let \(\alpha = (\alpha_1, \alpha_2)\), \(\alpha_i \geq 0\), be a double index, and let \(|\alpha| = \alpha_1 + \alpha_2\). In the case \(|\alpha| = 1\), the definition of the bilinear mapping (2.4)–(2.6) and (2.2) imply that
\[
\|\hat{\partial}^{\alpha}\partial F\|_{\infty,\hat{e}} \leq C h^2 \quad \text{and} \quad \|\hat{\partial}^{\alpha} \frac{1}{J} DF\|_{\infty,\hat{e}} \leq C.
\]
In the case \(|\alpha| = 2\) we have the estimates
\[
\|\hat{\partial}^{\alpha}\partial F\|_{\infty,\hat{e}} = 0 \quad \text{and} \quad \|\hat{\partial}^{\alpha} \frac{1}{J} DF\|_{\infty,\hat{e}} \leq C h.
\]

As a result, we get
\[
\|\hat{\partial}^{\alpha} B\|_{\infty,\hat{e}} \leq C \left( h \|\hat{K}^{-1}\|_{\infty,\hat{e}} + \|\hat{\partial}^{\alpha} \hat{K}^{-1}\|_{\infty,\hat{e}} \right),
\]
for \(|\alpha| = 1\), and
\[
\|\hat{\partial}^{\alpha} B\|_{\infty,\hat{e}} \leq C \left( h^2 \|\hat{K}^{-1}\|_{\infty,\hat{e}} + h \|\hat{\partial}^{\alpha-1} \hat{K}^{-1}\|_{\infty,\hat{e}} + \|\hat{\partial}^{\alpha} \hat{K}^{-1}\|_{\infty,\hat{e}} \right),
\]
for \(|\alpha| = 2\). Since \(\hat{K}^{-1} = K^{-1} \circ F\), using the chain rule and \(\|\hat{\partial}^{\alpha} F\|_{\infty,\hat{e}} \leq C h^{\|\alpha\|}\) for \(|\alpha| \leq 2\), we obtain
\[
\|\hat{\partial}^{\alpha} \hat{K}^{-1}\|_{\infty,\hat{e}} \leq C h^{\|\alpha\|} \|K^{-1}\|_{\|\alpha\|,\infty,\hat{e}}, \quad \|\alpha\| = 0, 1, 2,
\]
which implies
\[
\|\hat{\partial}^{\alpha} B\|_{\infty,\hat{e}} \leq C h^{\|\alpha\|} \|K^{-1}\|_{\|\alpha\|,\infty,\hat{e}}, \quad \|\alpha\| = 0, 1, 2,
\]
completing the proof. \(\square\)

**Lemma 4.5.** If \(K^{-1} \in W^{2,\infty}(\Omega)\), then
\[
\sum_{e} T_2 = 0, \tag{4.48}
\]
where $T_2$ is defined in (4.44) above.

**Proof:** Summing over all elements in (4.44), we have

$$
\sum_e T_2 = \sum_e \sum_{k=1,3} \int_{\ell_k} \phi(s) \frac{\partial}{\partial s} \left( (B\hat{u}) \cdot \hat{\tau}_k \right) \hat{v} \cdot \hat{n}_k \, ds.
$$

(4.49)

Using (2.7), we have that for any edge $\ell$

$$(B\hat{u}) \cdot \hat{\tau} = \frac{1}{J F[TK^{-1}DF^T][DF^{-1}D|\ell|DF^{-1} \tau] = |\ell|(K^{-1}u) \cdot \tau.$$ 

Therefore, using (2.9), the sum in (4.49) becomes

$$
\sum_e T_2 = \sum_e \sum_{k=1,3} |\ell_k|^2 \int_{\ell_k} \phi(s) \frac{\partial}{\partial s} \left( (K^{-1}u) \cdot \tau_k \right) v \cdot n_k \, ds.
$$

(4.50)

Since $v \in V^h$, $v \cdot n = 0$ on exterior edges and $v \cdot n$ is continuous across interior edges. The assumed regularity for $K$ and $u$ implies that $K^{-1}u$ and $\frac{\partial}{\partial s} (K^{-1}u)$ are continuous across interior edges. Note that each interior edge $\ell$ appears twice in the sum in (4.50), which now can be rewritten as a sum of interior edge integrals

$$
\sum_e T_2 = \sum_{\ell} |\ell|^2 \int_{\ell} \phi(s) \frac{\partial}{\partial s} \left( (K^{-1}u) \cdot \tau \right) [v \cdot n] \, ds = 0,
$$

where $[v \cdot n]$ denotes the jump in the normal component of $v$. $\square$

5. **Superconvergence to the average edge fluxes and at the edge midpoints.** We now discuss how the superconvergence result from Section 4 can be applied to obtain superconvergence for the computed velocity to the average edge fluxes and at the midpoints of the edges. Define, for any $v \in (H^1(\Omega))^2$,

$$
\forall e \in \mathcal{T}_h, \quad |||v|||^2_e = \sum_{k=1}^4 \left( \int_{\ell_k} v \cdot n_k \, ds \right)^2,
$$

(5.1)

$$
|||v|||^2 = \sum_{e \in \mathcal{T}_h} |||v|||^2_e.
$$

(5.2)

Using the well-known property of the Piola transformation [6],

$$
\int_v \cdot n \, ds = \int_{\hat{v}} \hat{v} \cdot \hat{n} \, d\hat{s}, \quad \forall v \in (H^1(\Omega))^2,
$$

(5.3)

and transforming to the reference element and back, it is easy to see that $||| \cdot |||$ is a norm on $V^h$ and there exist constants $c_1$ and $c_2$ independent of $h$ such that

$$
c_1 \|v\| \leq |||v||| \leq c_2 \|v\| \quad \forall v \in V^h.
$$

It is clear from (4.2) and (5.3) that $|||\Pi v - v||| = 0$ for any $v \in (H^1(\Omega))^2$. Therefore,

$$
|||u - u^h||| \leq |||\Pi u - u^h||| \leq c_2 \|\Pi u - u^h\| \leq Ch^2 \|u\|_2,
$$

(5.4)

using Theorem 4.2. This implies edgewise superconvergence of the computed velocity $u^h \cdot n$ to $\frac{1}{|\ell|} \int_{\ell} u \cdot n \, ds$ in a discrete $L^2$-sense.
Remark 5.1. The superconvergence result (5.4) implies similar superconvergence for $|||u - u^h|||_M$, with

$$|||v|||^2_M = \sum_{e \in T_h} \sum_{k=1}^4 |\ell_k|^2 (v \cdot n_k)^2(m_k),$$

where $m_k$ is the midpoint of $\ell_k$. Our choice of reporting the results in $||| \cdot |||$ is motivated by the fact that average fluxes are easier to measure than pointwise values, and therefore are of greater practical interest.

6. Numerical experiments. In this section, we present the details of the numerical implementation. Instead of solving saddle point problem (2.10), we reduce it to an equivalent system with a symmetric positive definite matrix using the standard hybridization technique.

Let $V^h$ be the restriction of $V$ to quadrilateral $e$ and $\Lambda^h_\ell$ be the space of constant functions over edge $\ell$. Define

$$\tilde{V}^h = \prod_e V^h_e, \quad \text{and} \quad \Lambda^h = \prod_\ell \Lambda^h_\ell.$$ 

Note that the normal component of $v^h \in V^h$ is continuous across interior mesh edges and $v^h \cdot n = 0$ on exterior edges. Therefore,

$$V^h = \left\{ \tilde{v}^h \in \tilde{V}^h : \sum_e (\mu^h, \tilde{v}^h \cdot n_e)_{\partial e} = 0 \quad \forall \mu^h \in \Lambda^h \right\},$$

where $n_e$ is the outward normal vector for quadrilateral $e$.

It has been shown by many authors (see, e.g. [6]) that the original formulation (2.10) is equivalent to the mixed-hybrid formulation: find $(\tilde{u}^h, p^h, \lambda^h) \in \tilde{V}^h \times W^h \times \Lambda^h$ such that

$$(\mathbf{K}^{-1} \tilde{u}^h, \tilde{v}^h)_{h,e} - (p^h, \text{div } \tilde{v}^h)_e + (\lambda^h, \tilde{v}^h \cdot n_e)_{\partial e} = 0, \quad \forall \tilde{v}^h \in \tilde{V}^h,$$

$$(\text{div } \tilde{u}^h, w^h)_e = (f, w^h)_e, \quad \forall w^h \in W^h,$$

$$\sum_e (\mu^h, \tilde{u}^h \cdot n_e)_{\partial e} = 0, \quad \forall \mu^h \in \Lambda^h.$$ (6.1)

System (6.1) can be written in matrix form as

$$\begin{pmatrix} M & B^T & C^T \\ B & 0 & 0 \\ C & 0 & 0 \end{pmatrix} \begin{pmatrix} u \\ p \\ \lambda \end{pmatrix} = \begin{pmatrix} 0 \\ f \\ 0 \end{pmatrix},$$ (6.2)

where

$$D = \begin{pmatrix} M & B^T \\ B & 0 \end{pmatrix}$$

is a block-diagonal matrix (after a permutation of columns and rows) with as many blocks as mesh elements. Each block is a $5 \times 5$ matrix. Therefore, vectors $u$ and $p$ can be explicitly eliminated from (6.2) resulting in a system

$$S \lambda = b,$$ (6.3)
where $S$ is a sparse symmetric positive definite matrix. For logically rectangular meshes, $S$ has at most 7 non-zero elements in each row and column. Its non-zero entries represent connections between edge-based unknowns belonging to the same cell.

![Fig. 6.1. Examples of meshes used in numerical experiments.](image)

Problem (6.3) was solved with the preconditioned conjugate gradient (PCG) method. In the numerical experiments, we used one V-cycle of the algebraic multigrid method [24] as a preconditioner. The stopping criterion for the PCG method was the relative decrease in the norm of the residual by a factor of $10^{-12}$.

We solved the boundary problem (1.1) with a known analytic solution

$$p(x, y) = x^3 y^2 + x \cos(x y) \sin(x),$$

and tensor coefficient

$$K(x, y) = \begin{pmatrix} (x + 1)^2 + y^2 & -xy \\ -xy & (x + 1)^2 \end{pmatrix}.$$  

It is pertinent to note here that the superconvergence result established in the previous section for the homogeneous Neumann boundary condition can be extended to the case of general Neumann boundary value problem.

*Table 6.1: Convergence rates for Example 1: Neumann boundary conditions*
In Example 1, the computational domain $\Omega$ is the unit square. The computational grid is constructed from a uniform rectangular grid via the mapping

$$x(\xi, \eta) = \xi + 0.06 \sin(2\pi \eta) \sin(2\pi \xi), \quad y(\xi, \eta) = \eta + 0.06 \sin(2\pi \eta) \sin(2\pi \xi),$$

where $0 < \eta, \xi < 1$, and subsequent random distortion of mesh node positions (see Fig. 6.1). The maximum value of the distortion is proportional to the square of the local mesh size, i.e. the resulting grid satisfies assumptions (2.2) and (2.3). We test both Neumann and Dirichlet boundary conditions. The results for the Neumann problem are shown in Table 6.1. The convergence rates were computed using the linear regression for the data in the rows for $1/h = 32, 64, 128, 256$. In addition to norm (5.2), we show the convergence rate in the discrete $L_\infty$-norm:

$$|||u - u^h|||_\infty = \max_{e_k} \left| \frac{1}{|e_k|} \int_{\partial e_k} (u \cdot n_k - u^h \cdot n_k) \, ds \right|,$$

where maximum is taken over all mesh edges. The convergence rates for the pressure variable are shown in the following discrete norms:

$$|||p - p^h|||_2 = \sum_{e_i \in T^h} |p(c_i) - p^h(c_i)|^2 |e_i|$$

and

$$|||p - p^h|||_\infty = \max_{e_i \in T^h} |p(c_i) - p^h(c_i)|,$$

where $c_i$ is the geometric center of element $e_i$. The use of the geometric center instead of the mass center is due to the following property of the MFD method. The method is exact for linear solutions when the pressure variable, $p(c_i)$, is evaluated at the geometric center $c_i$ [15]. The second order convergence rate is observed for both the pressure and velocity variables in the discrete $L_2$ and $L_\infty$ norms.

| $1/h$   | $|||u - u^h|||_\infty$ | $|||u - u^h|||_\infty$ | $|||p - p^h|||_\infty$ | $|||p - p^h|||_\infty$ |

| 64     | 2.39e-2         | 1.81e-3         | 1.26e-4         | 3.57e-5         |
| 128    | 1.27e-2         | 4.65e-4         | 3.26e-5         | 8.95e-6         |
| 256    | 6.55e-3         | 1.19e-4         | 8.26e-6         | 2.24e-6         |
| Rate   | 0.90            | 1.96            | 1.95            | 2.00            |

In Example 2, the computational domain $\Omega$ consists of three quadrilaterals (see Fig. 6.1). A sequence of grids is obtained by uniform refinement of these quadrilaterals. The left bottom corner of the domain is located at point $(1, 0)$. The results of our numerical experiments are shown in Table 6.3. We realize that the grid is only locally $h^2$-uniform. However, the second order convergence rate for the velocity variable in the $L_2$ norm is attained.
Table 6.3
Convergence rates for Example 2: Neumann boundary conditions

| \(1/h\) | \(||u - u^h||_\infty\) | \(||u - u^h||_p\) | \(||p - p^h||_\infty\) | \(||p - p^h||_p\) |
|---|---|---|---|---|
| 8  | 1.59e-1 | 1.08e-1 | 8.84e-3 | 5.05e-3 |

| 256| 6.06e-4 | 1.11e-4 | 1.48e-5 | 4.53e-6 |
| Rate | 1.61 | 2.00 | 1.94 | 2.01 |

7. Conclusion. We have proved the superconvergence estimate for the velocity variable on \(h^2\)-uniform quadrilateral grids when the exact integration of velocities is replaced by a novel 4-point quadrature rule. The theoretical results for the full diffusion tensor have been confirmed with numerical experiments.

Appendix A. Representation of the trapezoidal rule error.  
Lemma A.1. Let \(f(x, y)\) be a function defined on a rectangular domain \([a, b] \times [c, d]\). The trapezoidal rule error

\[
E(f) = \int_a^b \int_c^d f(x,y)dy\,dx - (f)_T
\]

can be represented as

\[
E(f) = (d-c) \int_a^b \frac{(x-a)(x-b)}{2} \frac{\partial^2}{\partial x^2} f(x,c) \, dx \\
+ (b-a) \int_c^d \frac{(y-c)(y-d)}{2} \frac{\partial^2}{\partial y^2} f(a,y) \, dy.
\]

Proof: Define a function

\[
g(x,s) := (x-s)_+ = \begin{cases} 
  x-s, & x \geq s, \\
  0, & x < s.
\end{cases}
\]

The Peano Kernel Theorem (see [23, p. 142, Theorem 5.2-3]) states that the error of the trapezoidal rule is given by

\[
E(f) = \int_a^b A_{2,0}(s) f^{(2,0)}(s,c) \, ds \\
+ \int_c^d A_{0,2}(t) f^{(0,2)}(a,t) \, dt \\
+ \int_a^b \int_c^d A_{1,1}(s,t) f^{(1,1)}(s,t) \, ds \, dt, 
\]

where \(f^{(i,j)}(x,y) = \frac{\partial^{i+j}}{\partial x^i \partial y^j} f(x,y)\) for \(i, j \geq 0\) and

\[
A_{2,0}(s) = E(g(x,s)), \quad A_{0,2}(t) = E(g(y,t)), \quad A_{1,1}(s,t) = E(1).
\]
The trapezoidal rule is exact for constant functions. Therefore, $E(1) = 0$ and $A_{1,1}(s, t) = 0$. Straightforward calculations give

$$A_{2,0}(s) = \int_a^b \int_c^d g(s, x) dx dy - \frac{(b - a)(d - c)}{4} \sum_{j=1}^4 g(x_j, s)$$

$$= (d - c) \left( \int_c^b (x - s) dx - \frac{b - a}{2} (g(a, s) - g(b, s)) \right)$$

$$= (d - c) \frac{(s - a)(s - b)}{2}. \quad (A.2)$$

Similarly, we get

$$A_{0,2}(t) = (b - a) \frac{(t - c)(t - d)}{2}. \quad (A.3)$$

A substitution of (A.2) and (A.3) into (A.1) completes the proof. □
